## Survey Methodology

The survey was designed and conducted by PRRI among a random sample of adults (age 18 and up) living in the United States and who are part of Ipsos's Knowledge Panel. The survey included a national sample ( $\mathrm{N}=1,016$ ) representing all 50 states. Interviews were conducted online between June 26 and 29, 2020. The survey was made possible by a generous grant from The Ford Foundation.

Respondents are recruited to the KnowledgePanel using an addressed-based sampling methodology from the Delivery Sequence File of the USPS - a database with full coverage of all delivery addresses in the U.S. As such, it covers all households regardless of their phone status, providing a representative online sample. Unlike opt-in panels, households are not permitted to "self-select" into the panel; and are generally limited to how many surveys they can take within a given time period.

The initial sample drawn from the KnowledgePanel was adjusted using pre-stratification weights so that it approximates the adult U.S. population defined by the latest March supplement of the Current Population Survey. Next, a probability proportional to size (PPS) sampling scheme was used to select a representative sample.

To reduce the effects of any non-response bias, a post-stratification adjustment was applied based on demographic distributions from the most recent American Community Survey (ACS). The post-stratification weight rebalanced the sample based on the following benchmarks: age, race and ethnicity, gender, Census division, metro area, education, and income. The sample weighting was accomplished using an iterative proportional fitting (IFP) process that simultaneously balances the distributions of all variables. Weights were trimmed to prevent individual interviews from having too much influence on the final results. In addition to an overall national weight, separate weights were computed for each state to ensure that the demographic characteristics of the sample closely approximate the demographic characteristics of the target populations. The state-level post-stratification weights rebalanced the sample based on the following benchmarks: age, race and ethnicity, gender, education, and income.

The margin of error for the national survey is +/- 3.2 percentage points at the $95 \%$ level of confidence. The design effect for the survey is 1.1. In addition to sampling error, surveys may also be subject to error or bias due to question wording, context, and order effects.

[^0]:    ${ }^{1}$ This survey relied on a slightly different question wording. The May 2015 question asked: "Do you think the recent killings of African American men by police in Ferguson, Missouri, New York City, and Baltimore are isolated incidents, or are they part of a broader pattern of how police treat African Americans?"
